Table of Measurements.

Washington, April 1, 1879.

## Hy H. GÄTKE.

Meligoland, March S, 1879.

## Professor S. F. Baird, Secretary Smithsonian Institution:

Dear Sir : I have dclayed answering your very kind communication till I might be able to inform you of the receipt of the box despatched
for me. It arrived two days ago, and many, many thanks for the contents thereof, which to me are rery valuable indeed.

By this mail I shall send off a small box with skins, all I had, and, as I fear, of very little value to yon. Perhaps the suite of Sylvia suecicu, Limn., may interest yon, as the females and male in winter dress are perfectly reliable. The other form, S. lencooyanea, Brehm, comes rery rarely so far north as Heligoland, and the few instances it has turned up from four to six weeks earlier than the succica in spring. I have sent for your examination a skin of Lanius major, Pall., with the alar whitemark extenting over the bases of primaries only, and which I suppose. from what I see in Richardson and Swainson's "Faun. Bor. Amer.," is coincident with their Lan. borcalis.* Perhaps we have here to deal with a case similar to that of Alauda alpestris, viz, a gradual extension westward fiom an originally American home. Up to October, 1847, A. ulpestris was here an excessively rare appearance, known only to a very few sportsmen; lout at the fall of that year there was a very great influx of birds from the east (Tema sabinii may be counted among the rest), and withothese A. alpestris appeared in such numbers that one young man succeeded in shooting above a score during one afternoon. Ever since, this species has been a numerous and regular bird of passage during October and November of each suceessive year. I have packed for you a male and female, which, as coming from the westernmost point almost of their now regular line of migration, may be of some interest for the sake of comparing with the original stock. $\dagger$ I saw once a skin from America, an old male bird, which was of a rather intense brick-red color round the shoudders and wing-coverts, whereas these parts with our birds are always of a pinkish, vinaceons tinge. If the above coloration with your birds be the prevalent one I should like much the possession of such an old male specimen. $\ddagger$ Amongst the Pipit suite there is one Anthus richardi, a regular antumnal visitant here, from the far east of Asia (Daouria), § and if of interest to you I will next fall try to proeure some more skins for yon.

I am greatly gratified at finding that many points of your obserrations|| form already a part of my mannseript. Your remark that "if

[^0]a region be deprived of its spring birds" proves rery strikingly the fact that over a wide range of latitude each individual resorts for propagation to the latitude where it was hatehed; that birds quit their winterquarters in succession as their individually more northerly home becomes habitable,-naturally the most northerly latest; and that, consequently, Middendorf's calculation of the rate of migration-flight must be fallacious, becanse the individuals he observed earlier in spring at a lower latitude were not the same he saw later not thirty degrees higher north, but were such as passed over the former, whilst they perhaps were beginning to construct their nests; therefore, the period that lay between observing the two conld not be made use of as a measme whereby to determine their pace of flight or adrance during a day.

That the direction of the course of wandering birds shond be influenced by river courses or mountain chains, is a point which I do not agree to, at least so far as Europe comes under contemplation. Here during the fall, the ronte of miscellaneous species is so varied that the two principal hosts eross each other at right angles; one great mass progressing due west from the farthest east of Asia (e. g., Authus richardi, Sylvia superciliosa), and continne their course to Heligoland, England, France, and Spain. Besides these, all the rare antumnal visitors come here from the far east of Asia, which proves that there must be with birds of these regions a strong inherent tendency to a western migration, even in species whose real winter-quarters are in the sonth of India down to the Sunda Isles, as, for instance, the two named above. This line of flight diverges abruptly to the north when approaching the Atlantie in England, Western France, and Spain; vide the immense numbers crossing the Straits of Gibraltar.

This westerly current is cut at right angles by another host coming simultaneously down from the extreme north of Emrope and Asia, and steering due south for their winter-quarters, viz: The Willow Warblers, Phylloscopus trochilus and rufus, which go from the North Cape of Scandinavia to the Cape of Good Hope; P. tristis and boreatis, from Northern European and Asiatic Russia down to the sonth of India and China. The latter, together with Falco rufipes, Motacilla citreola, Authus cervinus, Eimberiza aureola, and Limosa cinerca, all plentifnlly breeding so close to Heligoland as the Onega Dvina, Megin, and Petchora districts, but still never, or very rarely, turuing up here during their antumnal flights, proves in itself their sonthern course-withont the least western incli-nation-eren if they were not observed down the Ural, the Black Sea, Turkestan, \&c. The most striking instance of such a move is seen in Sylvia philomela, which breeds in the south of Sweden, and, nevertheless, has been observed here but once during the last forty years!

A few can be pointed ont as going from nortlieast to southwest, namely, Sylvia suecict and the Alauda alpestris. These, and all the others enumerated, joined by hosts of the more common "million" which are spread far and wide over the entire northern Palaeartic Region.

What, under such cireumstances, becomes of the routes of hirds by river courses or momntains? How many great rivers has Authus richardi to cross, almost all at right angles, during his autumnal tlight from Daouria to France and Spain ?

I maintain that the migratorial morement, particularly the vernal one, when in normal progress, is performed by the great majority of birds fin beyond the perception of man, and that what we see of the same are but the irregularities and interruptions thereof-brought abont by atmospheric agencies.
lour opinion that the spring line of flight is widely different from that of the fall, I most completely participate in. All the different rontes enmmerated in the foregoing are dropped, and a more or less direct course toward the polar regions adopted. The wide front of the winter-quarters, extending from the west of $\Lambda$ frica to the east of Chian, the Philippines, Borneo, \&c., concentrating during this northerly passage to less than half its original stretch.

A proot of this latter assertion is rendered by the fact that of all the eastern birds which visit Heligoland during their antmmal migration, none appear during their return jommes, the track to the south which terminated their western flight having bronght them to far lower latitules; while in spring, as they pursue a direct course to their northeru breeding grounds, they leave all these westem countries to their left.

While the "rare birds" here duriug antumn are, withont exception, eastern species, those of the spring are as miformly from the southeastGreece, Asia Minor, Turkestan, \&e. Singular it is, that almost no exceptional bird hats come here from the south or west, $i$. $e$., so far as the Old World is concerned. In what eminent manner the "far west" is represented, I have told you at an carlier period.

And this leads me to the route which American birds follow to Lurope. I do not much lean to the supposition that storms have in any considerable rlegree to do with such extra tours, and why Newton and others adrance so strongly the Greenland, Iceland, \&c., route, I cannot (omprehend. I fancy they never contemplated the possibility of a bird coming in a direct line from Newfoundland to Ireland; in other words. that a bird might be able to sustain an uninterrupted flight sufficient to carry it across the Atlantic. My rasearches have led me to the belief that such is not alone far from being impossible, but that the probability of such a fact, wonderful as it may appear, is borne ont by good evidence.

For instance, these old spring birds of these Sylvia succica which I send you, have wintered in the middle or north of Africa. During their venal migration, the first point north thereof where they are regularly found in considerable numbers is Heligoland, whilst during this time they are of the utmost rarity in all countries intervening between the

Mediterranean and the North Sea, upper Germany not excepted. This fact incontestably proves that these birds cross this distance in one uninterrupted tlight, and during one short spring night, viz, in 9 to 10 hours, which gives a rate of locomotion of 40 geographical miles per hour. Wonderful, incomprehensible, I admit, but still remaining a fact. The slow clumsy Royston Crow (Corvus cornix) crosses from here due west* over to England, at a rate of 27 geographical miles an hour, and resnlts of 25 miles have been furnished by the semi-domesticated Carrierpigeon. The distance from the north of Africa to Heligoland is equivalent to that from Newfomdland to Iceland, and therefore no objection whatever can be raised against your birds crossing over to us direct.

All this with plenty of evidence, and a great many points besides, is ready in manuscript snfficient to cover from fifty to sixty pages octavo print, and by the end of May I shall be ready for the press altogether.

I greatly count on your lenience, my dear sir, whilst allowing my pen to run on at such an unpardonable length, but perceiving from your contribution that you, like myself, have studied the grand theme of the migration in nature, which is quite a different matter from all learned treatises thereon worked out by the lamp of the studio, my holby felt so comfortable in your genial company that it bolted off with this unresisting tide.

Begging once more to pardon my having rentured on your time and patience at such umpardonable length, in more or less objectionable English thereto,

I remain, dear sir, jours, very truly,

Н. GÄTKE.

## DESCIEIPTIGN OF ALEPOCEIPIALUS BABRDII, A NEW SPECHES OF EISII FRSM THE DOEP-SEA FAUNA OF THE WESTERN ATLANTIC.

By G. HROWN GOODE arad TARLETON M. BEAN.
The National Museum has recently received from Mr. Christian Johnson, of the schooner William Thompson of Gloncester, a single specimen of an undescribed species of Alcpocephatus taken on the Grand Banks, at a depth of 203 fathoms. The only other known representative of this genus is the Alcpocephalus rostratus Risso, a member of the

[^1]
[^0]:    * This specimen is not $L$. borculis, but seems referable to the L. excubitor of Europe.R. Ridgway.
    $\dagger$ The examples sent ly Mr. Gaitke resemble very closely in their robust build and dark colors the specimens usually oltained in eastern North America in winter, but lave the yellow of the head more extendef, this color in fact invading eveu the whole pileum. They can easily be matched, however, even in this respect from a large series.-R. Ridgway.
    $\ddagger$ The specimen here alluded to was very likely the var. chrysolema of California and Mexico, whieh has, at all seasons, the vinaecous tints of the northern forms replaced by a rusty cinnamon color. (Conf. Hist. N. Am. B., II, pp. 1411-44.)-R. Ridgway.
    $\$$ Do not these east Asiatic species cross over the Pacific from Kamtchatka via the Aleutian Islants ?
    \| Conf. "The Distrilmtion and Migrations of North American Birds." Am. Jour. Scicuce \& Arts, XLI, 1866, 78-90, 184-192, 337-347.

[^1]:    * During the fall this line of migration, so far as it comes under observation here, day or night, is from due east to west, sometimes perhaps with the declination of a point to the south.
